## SPARK PLUG FOR AN INTERNAL COMBUSTION ENGINE, AND METHOD, 1 12 FOR PRODUCING A SPARK PLUG 3 Related Art 4 5 6 The invention concerns a spark plug for an internal combustion engine, 7 comprising a shell, an insulator located in the shell and composed of a sintered ceramic material, as well as a center electrode heat-fused into an insulator, and a 8 9 terminal stud that have an electrically conductive connection with each other and 10 are located in the insulator. The invention further concerns a method for 11 producing a spark plug. 12 Due to the different thermal expansions of platinum and ceramic material, spark 13 14 plugs comprising a platinum center electrode heat-fused into an insulator have a 15 slight gap between the ceramic and the center electrode that allows air or 16 combustion gases to penetrate. For this reason, the components in the interior of 17 the spark plug must be stable in the presence of these gases. It is therefore impossible, for example, to install a carbon-based burn-off resistor in the anterior 18 19 region of the spark plug on the combustion chamber side, because the carbon 20 would be oxidized at the high temperatures by the penetrating atmospheric 21 oxygen. Additionally, contact pins must be made of materials that are stable in the presence of the penetrating gases. Contact pins having high thermal 22 23 conductivity, e.g., those made of copper, can therefore not be used. 24 25 A spark plug is made known in WO 97/49153, about which it is proposed that the contact pin be replaced with an electrically conductive ceramic-metal mixture in 26 27 order to prevent mechanical stresses, because the coefficients of thermal 28 expansion would then be the same. 29 The object of the invention is to further develop a spark plug of the type 30

described initially such that a gas-tight, reliable seal is ensured that can be

31

produced cost-effectively. The object of the invention is further to create a 1 2 method for producing such a spark plug. 3 4 Advantages of the Invention 5 6 With the spark plug having the features in Claim 1, the insulator and the cermet have the same or similar material properties, which ensures sealing. The fact that 7 8 the material properties are the same yields advantages for production as well as 9 operation: insulator and cermet can be easily sintered together, because they 10 have the same shrinkage behavior. Since insulator and cermet also have the same thermal expansion, no gaps are produced as a result of different thermal 11 expansions. As a result of the good seal that is achieved, materials can be used 12 13 in the anterior region of the spark plug that are not sufficiently stable in the presence of air or combustion gases at the high temperatures occurring during 14 15 operation, e.g., resistors having carbon as the conductive phase or contact pins made of copper and having good thermal conductivity. Only a relatively small 16 17 quantity of metal is needed for the metallic phase of the cermet, which results in 18 low costs for the spark plug. 19 According to a preferred exemplary embodiment of the invention, it is provided 20 21 that the ceramic phase of the cermet is composed of Al<sub>2</sub>O<sub>3</sub>, and the metallic 22 phase is composed of platinum or a platinum alloy. This cermet can be easily 23 sintered together with the insulator, because it comprises the same sintering 24 properties as the insulator. 25 26 According to a preferred exemplary embodiment of the invention, it is provided 27 that a ceramic granulated material is used to produce the cermet, the granules of 28 which are provided with a surface coating of a material having good electrical 29 conductivity. Due to the difference in size between the granules of the granulated 30 material—which preferably have a diameter in the range between 90 µm and 150

um—and the pulverized material—the particles of which are less than 10 μm in

31

size, a ceramic micro-structure results after sintering having a network of thin 1 metal tracks, e.g., made of platinum, that ensures sufficient electrical conductivity ،2 despite the small quantity of metal used. It is sufficient, for instance, for the 3 metallic phase of the cermet to constitute a quantity between 10 and 15 % by 4 volume. The precious metal that is preferably used is therefore used sparingly. 5 6 Reference is made to the explanations hereinabove with regard for the 7 advantages achieved with the method according to the invention. 8 9 According to a preferred exemplary embodiment of the method, it is provided that 10 11 the granules of the ceramic granulated material are coated with the material having good electrical conductivity by stirring in a diluted suspension. In this 12 fashion, the granules can be coated with the electrically conductive material, e.g., 13 14 platinum, in cost-effective fashion, so that the electrically conductive network is 15 produced in the interior of the cermet after the granulated material is sintered. As an alternative, the material having good electrical conductivity can also be 16 applied to the granules of the granulated material using an organic binding agent, 17 for instance, or it can be applied via vapour deposition or sputtering. 18 19 20 Brief Description of the Drawing 21 22 The invention is described below using a preferred exemplary embodiment 23 shown in the attached drawings. 24 25 Figure 1 shows a partial sectional view of a spark plug according to the 26 invention: 27 - Figure 2 shows an enlarged view of a section in Figure 1: - Figure 3 shows an enlarged micrograph of a part of the insulator of the 28 29 spark plug according to the invention with center electrode heat-fused into 30 an insulator; 31 Figure 4 shows an enlarged section of the micrograph in Figure 3.

## Detailed Description of the Exemplary Embodiment

، 2

A spark plug 10 is shown in Figure 1 that comprises a shell 12 composed of metal and having threads 14, by means of which the spark plug can be screwed into a bore in a cylinder head of an internal combustion engine. An insulator 16 is housed in the interior of the shell 12, which is composed of a sintered ceramic material such as Al<sub>2</sub>O<sub>3</sub>. A center electrode 18 and a terminal stud 22 that have an electrically conductive connection with each other are housed in the interior of the insulator. A spark can therefore be produced in known fashion between the center electrode 18 and ground electrodes 26 attached to the shell 12 by applying a voltage potential between a terminal nut 24 screwed onto the terminal stud 22 and the shell 12.

The seal and the electrically conductive connection between terminal stud 22 and center electrode 18 is designed as follows: a cermet 28 abuts the center electrode 18, which is followed by a burn-off resistor 30 (with a contact set between them, if necessary), followed by a contact set 32 that is penetrated by the terminal stud 22.

The gas-tight seal is described below in detail using Figures 2 through 4.

The insulator 16 comprises an offset bore in its interior, the anterior end 36 of which houses the center electrode. The center electrode—which is preferably composed of fine grain-stabilized platinum or a fine grain-stabilized platinum alloy—comprises a nail head 38 that rests on the shoulder toward the greater bore diameter. The center electrode is heat-fused into the insulator and is sealed over the nail head by the cermet 28 and additionally fixed in position. The cermet 28 is composed of ceramic material and a metallic phase. The same material is used for the ceramic phase as for the insulator, i.e., Al<sub>2</sub>O<sub>3</sub> having the known additives of sintering auxiliary agents, such as SiO<sub>2</sub>, CaO, MgO, etc. Platinum or a platinum alloy is used for the metallic phase.

1 The cermet is produced starting with a granulated material of the insulator 2 material having a granule size between 90 μm and 150 μm. The granules of the 3 ceramic granulated material are then coated with the platinum or platinum alloy serving as electrical conductor, e.g., by stirring in a mixer with a diluted platinum 4 suspension, and then drying. The platinum or the platinum alloy is present in the 5 suspension in powder form; the individual granules are less than 10 µm in size. 6 In this fashion, granules are obtained that are coated with a small quantity of 7 8 platinum or the platinum alloy. In order to achieve the electrical conductivity 9 needed later on, it has proven sufficient if the quantity of platinum or platinum 10 alloy constitutes 10 to 15 % by volume of the cermet. 11 12 The ceramic granulated material coated in this fashion is filled into the 13 insulator—which was produced using a usual method and may have been preannealed at a temperature of 1000° C to increase hardness—so that it lies above 14 15 the nail head 38 of the center electrode 18 inserted in the location hole 38. The granulated material is then compressed using a stamp using a force of 16 approximately 100 to 150 N. Finally, the insulator is sintered together with the 17 18 granulated material at approximately 1600° C, in the usual fashion. This results in 19 a very good bond between the insulator and the cermet, because the same material is used as the basic material for the cermet as for the insulator, and 20 21 good electrical conductivity of the cermet is produced due to the platinum or the 22 platinum alloy, because a network of thin tracks of platinum or the platinum alloy is produced during sintering. This is shown in the micrographs in Figures 3 and 4. 23 24 A nearly uniform micro-structure of insulator 16 and cermet 28 is produced, 25 which differs only in terms of the platinum or platinum-alloy tracks present in the 26 cermet 28. 27 28 Since the same material is used for the ceramic phase of the cermet as for the 29 insulator, a particularly good seal is produced on the back side of the center 30 electrode 18. This seal is also maintained over long service lifes, because the 31 cermet and the insulator have the same thermal expansion, so no thermal

stresses and cracks or gaps resulting therefrom can occur. Carbon can therefore be used, for example, as electrically conductive material for the burn-off resistor 30, even though this material is not sufficiently stable in the presence of air or combustion gases at the operating temperatures; the seal is so reliable that the carbon does not come in contact with the air or the combustion gases.
